Problem 1

The number of molecules, N, found in a sample of a compound with mass M is

$$N(\cdot) = \frac{M(\cdot)N_A}{m(\cdot)}$$

where m is the molar mass of the compound, and N_A is Avogadro's number ($N_A = 6.022 \times 10^{23}$ molecules per mole). Where each actinide isotope is found only once in a molecule of its respective oxide, N also gives the number of atoms of an isotope in the sample.

To find N, we begin by finding the masses of the compounds in the fuel. We can decompose the total mass of the fuel, M_f , into its mixed oxide components:

$$M_f = M(UO_2) + M(PuO_2).$$

Given a weight percent for plutonium, w_P , we note that $w_U = 1 - w_P$ and so calculate the total masses of both the UO_2 and the PuO_2 to be

$$M(\text{UO}_2) = (1 - w_P)M_f$$
$$M(\text{PuO}_2) = w_P M_f.$$

We are told that the uranium is all ²³⁸U, so

$$M(^{238}UO_2) = M(UO_2) = (1 - w_P)M_f.$$

iiiiiii HEAD The weight percents of the plutonium isotope oxides are also given (as a fraction of total plutonium oxide). Using 239 PuO₂ as an example

$$M(^{239}\text{PuO}_2) = w_{\text{P9}}M(\text{PuO}_2) = w_{\text{P9}}w_{\text{P}}M_f.$$

Next, we must determine the molar masses of the various oxides. For uranium,

$$m(^{238}UO_2) = m(^{238}U) + 2m(O),$$

and similarly for plutonium.

When we combine the total and molar masses to determine the total number of atoms for each isotope, we find:

 $6.69{\times}10^{20}$ atoms of $^{238}{\rm U}$

 4.65×10^{20} atoms of 239 Pu

 1.45×10^{20} atoms of 240 Pu

 3.84×10^{19} atoms of ²⁴¹Pu

 1.78×10^{19} atoms of 242 Pu

(for full calculation, see Jupyter notebook, attached)

1.1 Problem 1

The number of molecules, N, found in a sample of a compound with mass M is

$$N(\cdot) = \frac{M(\cdot)N_A}{m(\cdot)}$$

where m is the molar mass of the compound, and N_A is Avogadro's number ($N_A = 6.022 \times 10^{23}$ molecules per mole). Since each actinide isotope is found only once in a molecule of its respective oxide, N also gives the number of atoms of an isotope in the sample.

To find N, we begin by finding the masses of the compounds in the fuel. We can decompose the total mass of the fuel, M_f , into its mixed oxide components:

$$M_f = M(UO_2) + M(PuO_2).$$

Given a weight percent for plutonium, w_P , we note that $w_U = 1 - w_P$ and so calculate the total masses of both the UO_2 and the PuO_2 to be

$$M(UO_2) = (1 - w_P)M_f$$
$$M(PuO_2) = w_P M_f.$$

The mass of the oxide component for a given isotope is given by

$$M(^{i}XO_{2}) = w_{i}M(XO_{2})$$

where w_i is the weight percent of the oxide of isotope iX out of element X.

Next, we must determine the molar masses of the various oxides. In general,

$$m(^{i}XO_{2}) = m(^{i}X) + 2m(O),$$

Finally, we use both the total mass of a compound with its molar mass in the original formula, using provided or tabulated values:

```
In [9]: # Tabulated molar masses [g/mol]
        m = \{ 'U238' : 238.051,
             'Pu239': 239.052,
             'Pu240': 240.054,
             'Pu241': 241.057,
             'Pu242': 242.059,
             '016': 15.995
            }
In [10]: # Assume 1 gram of total fuel
         M_f = 1
         isotopes = ['U238','Pu239','Pu240','Pu241','Pu242']
         for i in isotopes:
             M_i_ox = mass_isotope_oxide(w[i], mass_oxide(w_p, M_f))
             m_i_ox = molar_mass_isotope_oxide(m[i], m['016'])
             N = molecule_count(M_i_ox, m_i_ox)
             print(i, ': ', N)
```

U238: 6.690095207764747e+20
